The Ising Model

Consider,

$$\mathbb{P}_{\beta, B}^N(\sigma = \tau) := \frac{1}{Z_N(\beta, B)} \exp \left(\frac{\beta}{2d_N} \tau' A(G_N) \tau + B \sum_{i=1}^N \tau_i \right) \quad (1)$$

for $\tau \in \{-1, 1\}^N$.

$A(G_N)$ is the adjacency matrix of:

- Lattice graph in d dimensions: Original paper by Ising (1925) considered the one dimensional lattice. It was proposed by Lenz to model sharp phase transition of ferromagnetic properties (at Curie temperature).
- Complete graphs: Curie-Weiss model.
- Random graphs: Erdős Rényi, random regular, etc.

Applications

- 1 Modeling dynamics of interactive systems –e.g., atomic motion in lattice gas, earthquake dynamics, image segmentation, etc.

Statistical motivation

Motivating Theorem, Barndorff [2014]

Suppose $\alpha \in \mathbb{R}$, $\phi : \mathbb{R}^n \mapsto \mathbb{R}$ and $\mathcal{P}_\mu(\mathbb{R}^n)$: prob. measures on \mathbb{R}^n , $\ll \mu$. Then,

$$\max_{\mathcal{P}_\mu(\mathbb{R}^n)} - \int p(x) \log p(x) d\mu(x) \text{ subject to } \mathbb{E}_p \phi(\cdot) = \alpha$$

is attained at uniquely at $p_\theta^*(x) \propto \exp(\theta\phi(x))$ where $\mathbb{E}_{p_\theta^*} \phi(\cdot) = \alpha$.

is attained at uniquely at $p_\theta^*(x) \propto \exp(\theta \phi(x))$ where $\mathbb{E}_{p_\theta^*} \phi(\cdot) = \alpha$.

Put constraints on pairwise weighted correlations (simple interaction): $\sum_{i,j} w_{ij} \sigma_i \sigma_j$ (from the data). Then $p^*(\sigma) \propto \exp(\beta \sum_{i,j} w_{ij} \sigma_i \sigma_j)$ ((1) with $B = 0$).

An example of “Approximately regular” graphs

- Suppose $G_N \sim$ Erdős Rényi (N, p_N) graph, with $p_N \gg \log N/N$.
- In this case,
$$\sum_{i=1}^N (d_i/\bar{d}_N - 1)^2 = o_{\mathbb{P}}(N/\log N) = o_{\mathbb{P}}(N)$$
 (rather weak notion of regularity).

An example of “Approximately regular” graphs

- Suppose $G_N \sim \text{Erdős Rényi } (N, p_N)$ graph, with $p_N \gg \log N/N$.
- In this case,
$$\sum_{i=1}^N (d_i/\bar{d}_N - 1)^2 = o_{\mathbb{P}}(N/\log N) = o_{\mathbb{P}}(N)$$
 (rather weak notion of regularity).
- Our methods also work under random graphs, such as Erdős Rényi above.
- Lower bounds on the “extent of regularity”.

Variational Approach to “universality”

- Given $Q_N(\mathbf{x})$ be a discrete measure supported on $\{-1, 1\}^N$. Then $D(Q_N \| P_N)$ equals,

$$\begin{aligned} & \sum_{\mathbf{x} \in \{-1, 1\}^N} Q_N(\mathbf{x}) \log \frac{Q_N(\mathbf{x})}{P_N(\mathbf{x})} \\ &= \sum_{\mathbf{x} \in \{-1, 1\}^N} Q_N(\mathbf{x}) \log Q_N(\mathbf{x}) - \frac{\beta}{2} \sum_{\mathbf{x} \in \{-1, 1\}^N} Q_N(\mathbf{x}) \mathbf{x}' A_N \mathbf{x} \\ & \quad - B \sum_{\mathbf{x} \in \{-1, 1\}^N} Q_N(\mathbf{x}) \mathbf{1}' \mathbf{x} + \log Z_N(\beta, B) \end{aligned}$$

Variational Approach towards “universality”

- As $D(\cdot\|\cdot) \geq 0$,

$$\log Z_N(\beta, B) \geq \mathbb{E}_{\mathbb{Q}_N} \left\{ \frac{\beta}{2} \mathbf{x}' A_N \mathbf{x} + B \mathbf{1}' \mathbf{x} - \log \mathbb{Q}_N(\mathbf{x}) \right\}.$$

for any $\mathbb{Q}_N(\cdot)$.

Variational Approach towards “universality”

- As $D(\cdot\|\cdot) \geq 0$,

$$\log Z_N(\beta, B) \geq \mathbb{E}_{\mathbb{Q}_N} \left\{ \frac{\beta}{2} \mathbf{x}' A_N \mathbf{x} + B \mathbf{1}' \mathbf{x} - \log \mathbb{Q}_N(\mathbf{x}) \right\}.$$

for any $\mathbb{Q}_N(\cdot)$.

- Choose $\mathbb{Q}_N(\mathbf{x})$ as the measure induced by independent ± 1 rv's with mean vector $\mathbf{m} := (m_1, m_2, \dots, m_N)$.

$$\log Z_N(\beta, B) \geq \frac{\beta}{2} \mathbf{m}' A_N \mathbf{m} + \sum_{i=1}^N (B m_i - I(m_i))$$

for any \mathbf{m} , where $I(x) := \frac{1+x}{2} \log \frac{1+x}{2} + \frac{1-x}{2} \log \frac{1-x}{2}$ is the binary entropy function.

Variational Approach towards “universality”

- We are interested in

$$\sup_{\mathbf{m}} \frac{\beta}{2} \mathbf{m}' A_N \mathbf{m} + \sum_{i=1}^N (B m_i - I(m_i))$$

which (as of now) depends on the underlying graph.

Variational Approach towards “universality”

- We are interested in

$$\sup_{\mathbf{m}} \frac{\beta}{2} \mathbf{m}' A_N \mathbf{m} + \sum_{i=1}^N (B m_i - I(m_i))$$

which (as of now) depends on the underlying graph.

- Now restrict to “regular graphs”. By **(P2)**,

$$\begin{aligned} & \sup_{\mathbf{m}} \left\{ \frac{\beta}{2} \mathbf{m}' A_N \mathbf{m} + \sum_{i=1}^N (B m_i - I(m_i)) \right\} \\ & \leq \sup_{\mathbf{m}} \sum_{i=1}^N \left\{ \frac{\beta}{2} m_i^2 + B m_i - I(m_i) \right\} \end{aligned}$$

which is decoupled.

Variational Approach towards “universality”

- The supremum on RHS is attained at $\mathbf{m} = t\mathbf{1}'$ where $t > 0$ satisfies $t = \tanh(\beta t + B)$. Therefore,

$$\begin{aligned} & \sup_{\mathbf{m}} \left\{ \frac{\beta}{2} \mathbf{m}' A_N \mathbf{m} + \sum_{i=1}^N (B m_i - I(m_i)) \right\} \\ & \leq N \left\{ \frac{\beta t^2}{2} + B t - I(t) \right\} \end{aligned}$$

- Combining above observations,

$$\frac{\log Z_N(\beta, B)}{N} \geq \frac{\beta t^2}{2} + Bt - I(t) \quad (3)$$

for regular graphs. The RHS above is often called “mean-field prediction”.

- Note that the right hand side no longer depends on A_N (“universality”) for the whole spectrum of (β, B) .

Actual Theorem

Theorem in Basak and Mukherjee [2017] (universality)

Under model (1) (and **(A1)**), if G_N is a sequence of “approximately” regular graphs, with $\bar{d}_N \xrightarrow{N \rightarrow \infty} \infty$, then:

$$\frac{1}{N} \log Z_N(\beta, B) \xrightarrow{N \rightarrow \infty} \sup_x \left(\frac{\beta}{2} x^2 + Bx - I(x) \right).$$

Weak Limits

Proposition (universality)

Under model (1) (and **(A1)**), if G_N is a sequence of “approximately” regular graphs, with $\bar{d}_N \xrightarrow{N \rightarrow \infty} \infty$, then:

- 1 If $\beta \leq 1$, $B = 0$ or $B > 0$, then $T_N \xrightarrow{\mathbb{P}_{\beta, \mathbb{B}}^N} t$.
- 2 If $\beta > 1$, $B = 0$ and G_N , then

$$T_N \xrightarrow{\mathbb{P}_{\beta, \mathbb{B}}^N} \begin{cases} t & \text{w.p. } 0.5 \\ -t & \text{w.p. } 0.5 \end{cases}.$$

Here $t \geq 0$ is the maximizer of the RHS in (3). For non-uniqueness, **(A2)** is required.

Is \sqrt{N} an artifact?

Can we have universal behaviour for $\bar{d}_N \leq \sqrt{N}$?
No! (\sqrt{N} is tight).

Eg. Consider $\bar{d}_N = \lambda\sqrt{N}$ and G_N as a disjoint union of N/\bar{d}_N complete graphs, each of size \bar{d}_N , then we prove (for $B > 0$):

$$\sqrt{N}(T_N - t) \xrightarrow{w} \mathcal{N}\left(\frac{\mu(\beta, B)}{\lambda}, \frac{1 - t^2}{1 - \beta(1 - t^2)}\right).$$

$\mu(\beta, B) \neq 0$ and free of λ .

No universal behaviour for fluctuations?

Does this mean, at the fluctuation level, the entire asymptotic regime (from Basak and Mukherjee [2017]) cannot be reproduced?

Under model (1),

$$\mathbb{E}[\sigma_i | \sigma_1, \dots, \sigma_{i-1}, \sigma_{i+1}, \dots, \sigma_N] = \tanh(\beta m_i + B)$$

where $m_i = \sum_j a_{ij} \sigma_j$ (average response from neighbours).

No universal behaviour for fluctuations?

Does this mean, at the fluctuation level, the entire asymptotic regime (from Basak and Mukherjee [2017]) cannot be reproduced?

Under model (1),

$$\mathbb{E}[\sigma_i | \sigma_1, \dots, \sigma_{i-1}, \sigma_{i+1}, \dots, \sigma_N] = \tanh(\beta m_i + B)$$

where $m_i = \sum_j a_{ij} \sigma_j$ (average response from neighbours).

Look at $S_n := \frac{1}{N} \sum_i (\sigma_i - \tanh(\beta m_i + B))$. For bounded \bar{d}_N , S_N was analysed in Comets and Janžura [1998].

Conditionally centered fluctuation

Theorem 2 (universality)

Under model (1) (and **(A1)**), if G_N is a sequence of “approximately” regular graphs, with $\bar{d}_N \xrightarrow{N \rightarrow \infty} \infty$, then for any (β, B) :

$$\sqrt{N}S_N = \frac{1}{\sqrt{N}} \sum_i (\sigma_i - \tanh(\beta m_i + B)) \xrightarrow{d} \mathcal{N}(0, \tau^2).$$

Here $\tau^2 = (1 - t^2)(1 - \beta(1 - t^2))$. For the non-uniqueness regime, **(A2)** is required.

Conditionally centered fluctuation

Theorem 2 (universality)

Under model (1) (and **(A1)**), if G_N is a sequence of “approximately” regular graphs, with $\bar{d}_N \xrightarrow{N \rightarrow \infty} \infty$, then for any (β, B) :

$$\sqrt{N}S_N = \frac{1}{\sqrt{N}} \sum_i (\sigma_i - \tanh(\beta m_i + B)) \xrightarrow{d} \mathcal{N}(0, \tau^2).$$

Here $\tau^2 = (1 - t^2)(1 - \beta(1 - t^2))$. For the non-uniqueness regime, **(A2)** is required.

When $\beta = 1, B = 0$ however, $\tau = 0$. We expect in that case, $N^{3/4}S_n = O_p(1)$.

“Ising” on the cake?

For Theorem 1, we actually get Berry-Esseen equivalents for the weak-convergence, e.g., if $\beta < 1$, $B = 0$ or $B > 0$, then:

$$\sup_x |\mathbb{P}(\sqrt{N}(T_N - t) \leq x) - \mathbb{P}(\sigma Z \leq x)| \lesssim \sqrt{N}/\bar{d}_N.$$

Here σ^2 is the asymptotic variance from Theorem 1. Same rates hold for the other regimes of (β, B) .

“Ising” on the cake?

For Theorem 1, we actually get Berry-Esseen equivalents for the weak-convergence, e.g., if $\beta < 1$, $B = 0$ or $B > 0$, then:

$$\sup_x |\mathbb{P}(\sqrt{N}(T_N - t) \leq x) - \mathbb{P}(\sigma Z \leq x)| \lesssim \sqrt{N}/\bar{d}_N.$$

Here σ^2 is the asymptotic variance from Theorem 1. Same rates hold for the other regimes of (β, B) .

- 1 If $\bar{d}_N \approx N$ (dense graphs), then $\text{RHS} \lesssim N^{-1/2}$.
- 2 If $\bar{d}_N \approx \sqrt{N}$, then $\text{RHS} \lesssim O(1)$ (we know that the result is not true in this regime).

More implications

- 1 In terms of parameter estimation (β, B) , we improve the existing results from Ghosal and Mukherjee [2018] and Bhattacharya and Mukherjee [2018] (e.g., Extending impossibility regimes).

More implications

- 1 In terms of parameter estimation (β, B) , we improve the existing results from Ghosal and Mukherjee [2018] and Bhattacharya and Mukherjee [2018] (e.g., Extending impossibility regimes).
- 2 We prove that, marginally,

$$\sqrt{N}(\tilde{\beta} - \beta) \xrightarrow{d} \mathcal{N}\left(0, \frac{1 - \beta(1 - t^2)}{1 - t^2}\right)$$

$$\sqrt{N}(\tilde{B} - B) \xrightarrow{d} \mathcal{N}\left(0, \frac{1 - \beta(1 - t^2)}{1 - t^2}\right)$$

for certain regimes. $\tilde{\beta}$ represents pseudo-likelihood estimator (for B known), see Besag [1986].

Implications continued

Our results extend to graphs which are “approximately” regular (with counterexamples showing tightness for the extent of regularity). In addition to deterministic graphs, we also cover:

- 1 Random d -regular graphs.
- 2 $G_N :=$ Erdős-Rényi graph with parameters (N, p_N) if $p_N \gg (\log N)N^{-1}$.
- 3 $G_N :=$ stochastic block model with balanced, possibly growing, block sizes.
- 4 W -random graphons (where $W(\cdot)$ is regular).
